

# Finite Complete Suites for CSP Refinement Testing

Ana Cavalcanti, Wen-ling Huang, Jan Peleska, and Adenilso Simao

**Abstract.** In this paper, new contributions to testing Communicating Sequential Processes (CSP) are presented, with focus on the generation of complete, finite test suites. A test suite is complete if it can uncover every conformance violation of the system under test with respect to a reference model. Both reference models and implementation behaviours are represented as CSP processes. As conformance relation, we consider trace equivalence and trace refinement, as well as failures equivalence and failures refinement. Complete black-box test suites here rely on the fact that the SUT's true behaviour is represented by a member of a fault-domain, that is, a collection of CSP processes that may or may not conform to the reference model. We define fault domains by bounding the number of excessive states occurring in a fault domain member's representation as a normalised transition graph, when comparing it to the number of states present in the graph of the reference model. This notion of fault domains is quite close to the way they are defined for finite state machines, and these fault domains guarantee the existence of *finite* complete test suites.

**Keywords:** model-based testing, complete testing theories, finite state machines

## 1. Introduction

### *Motivation*

Model-based testing (MBT) is an active research field that is currently evaluated and integrated into industrial verification processes by many companies. This holds particularly for the embedded and cyber-physical systems domain. While MBT is applied in different flavours, we consider the most effective variant to be the one where test cases and concrete test data, as well as checkers for the expected results (*test oracles*), are automatically generated from a reference model: it guarantees the maximal return of investment for the time and effort invested into creating the test model. The test suites generated in this way, however, usually have different test strength, depending on the generation algorithms applied.

For the safety-critical domain, test suites with guaranteed fault coverage are of particular interest. For black-box testing, guarantees can be given only if certain hypotheses are satisfied. These hypotheses are usually specified by a *fault domain*: a set of models that may or may not conform to the SUT. The so-called *complete* test strategies guarantee to uncover every conformance violation of the SUT with respect to a reference model, provided that the true SUT behaviour is captured by a member of the fault domain.

Generation methods for complete test suites have been developed for various modelling formalisms. In this paper, we use *Communicating Sequential Processes (CSP)* [Hoa85, Ros10]; this is a mature process-algebraic approach that has been shown to be well-suited for the description of reactive control systems in many publications over almost five decades. Industrial success has also been reported.

## Contributions

This paper complements work published by two of the authors in [CdSS17]. There, fault domains are specified as collections of processes refining a “most general” fault domain member. With this concept of fault domains, complete test suites may be finite or infinite. While this gives important insight into the theory of complete test suites, we are particularly interested in finite suites when it comes to their practical application.

Therefore, we present a complementary approach to the definition of CSP fault domains in this paper. To this end, we observe that every finite-state CSP process can be semantically represented as a finite normalised transition graph, whose edges are labelled by the events the process engages in, and whose nodes are labelled by minimal acceptances or, alternatively, maximal refusals [Ros94]. The maximal refusals express the degree of nondeterminism that is present in a given CSP process state that is in one-one-correspondence to a node of the normalised transition graph. Inspired by the way that fault-domains are specified for finite state machines (FSMs), we define them here as the set of CSP processes whose normalised transition graphs do not exceed the size of the reference model’s graph by more than a give constant.

Our main contributions in this paper are as follows.

1. It is proven that for fault domains of the described type, complete test suite generation methods can be given for verifying (1) trace equivalence, (2) trace refinement, (3) failures equivalence, and (4) failures refinement.
2. We prove that finite complete test suites can be generated in all four cases, when using the fault domains based on the size of the members’ normalised transition graphs.
3. We present test suite generation techniques for each of the four conformance relations by translating algorithms originally elaborated for the FSM domain into the CSP world. This translation preserves the completeness properties that have previously been established for the FSM domain by other authors.

The possibility to translate complete test suites between different formalisms (here FSMs and CSP processes) has been investigated before by two of the authors [HP17].

## Overview

@todo

## 2. Preliminaries

In this section, we present the background material relevant to our work.

### 2.1. Complete Test Suites

We use the term *signature* to denote a collection of comparable models represented in an arbitrary formalism. In this article, signatures represent sets of finite state machines over fixed input and output alphabets, or CSP processes with finite state, represented by their normalised transition graphs (see Section 2.3).

Given a signature  $Sig$  of models, a *fault model*  $\mathcal{F} = (M, \leq, Dom)$  specifies a *reference model*  $M \in Sig$ , a *conformance relation*  $\leq \subseteq Sig \times Sig$  between models, and a *fault domain*  $Dom \subseteq Sig$ . This terminology follows [PYB96], where fault models have been originally introduced in the context of testing of finite state machines. Note that fault domains may contain both models conforming to the reference model and models violating the conformance relation. Note further that the reference model  $M$  is not necessarily a member of the fault domain, although a model of the SUT behaviour is. For example,  $M$  could be nondeterministic, while only deterministic implementation behaviours might be considered in the fault domain.

Let  $TC(Sig)$  denote the set of all *test cases* applicable to elements of  $Sig$ . This abstract notion of test case requires only the existence of a relation  $pass \subseteq Sig \times TC(Sig)$ . For  $(M, U) \in pass$ , the infix notation  $M \text{ pass } U$  is used, and interpreted as ‘*model  $M$  passes the test case  $U$* ’. If  $(M, U) \notin pass$  holds, this is abbreviated by  $M \text{ fail } U$ . Our specific notion of test cases for CSP models is elaborated in Section 3.2.

A *test suite*  $TS \subseteq TC(Sig)$  denotes a set of test cases. A model  $M$  *passes the test suite*  $TS$ , also written as  $M \text{ pass } TS$ , if, and only if,  $M \text{ pass } U$  for all  $U \in TS$ . A test suite  $TS$  is called *complete* for fault model  $\mathcal{F} = (M, \leq, Dom)$ , if, and only if, the following properties hold.

FiXme

Warning: alcc:  
I miss a  
paragraph that  
discusses what  
is difficult. So  
far, it sounds  
like just  
application of  
known results,  
which is not  
true.

1. If a member  $M'$  of the fault domain conforms to the reference model  $M$ , it passes the test suite, that is,

$$\forall M' \in Dom : M' \leq M \Rightarrow M' \text{ pass TS}$$

This property is usually called *soundness* of the test suite.

2. If a member of the fault domain passes the test suite, it conforms to the reference model, that is,

$$\forall M' \in Dom : M' \text{ pass TS} \Rightarrow M' \leq M$$

This property is usually called *exhaustiveness*.

A test suite TS is *finite* if it contains finitely many test cases and every test case  $U \in \text{TS}$  is finite in the sense that it terminates after a finite number of steps. It is trivial to see that, if TS is complete for  $\mathcal{F} = (M, \leq, Dom)$  and  $Dom' \subseteq Dom$ , then TS is also complete for  $\mathcal{F}' = (M, \leq, Dom')$ .

## 2.2. Translation of Test Cases and Test Suites

Let  $Sig_1$  and  $Sig_2$  be two signatures with conformance relations  $\leq_1$  and  $\leq_2$ , and test case relations  $\text{pass}_1$  and  $\text{pass}_2$ , respectively. A function  $T : Sig_1 \rightarrow Sig_2$  defined on a sub-domain  $Sig_1 \subseteq Sig_1$  is called a *model map*, and a function  $T^* : \text{TC}(Sig_2) \rightarrow \text{TC}(Sig_1)$  is called a *test case map*. Note that models and test cases are mapped in opposite directions (see Fig. 1). Also, for  $T$ , we consider a sub-domain of  $Sig_1$  since it may be the case that the map is not defined for the whole of  $Sig_1$ . For example, in our case, we are interested in finite-state CSP processes only and their translation to graphs described in the next section.

The pair  $(T, T^*)$  fulfils the *satisfaction condition* if, and only if, the following conditions are fulfilled.

**SC1** The model map is compatible with the conformance relations under consideration, in the sense that

$$\forall S, S' \in Sig_1 : S' \leq_1 S \Leftrightarrow T(S') \leq_2 T(S),$$

so the left-hand side diagram in Fig. 1 commutes due to the fact that  $T; \leq_2 = \leq_1; T$ .<sup>1</sup>

**SC2** The model map and the test case map preserve the *pass*-relationship in the sense that

$$\forall S \in Sig_1, U \in \text{TC}(Sig_2) : T(S) \text{ pass}_2 U \Leftrightarrow S \text{ pass}_1 T^*(U),$$

so the right-hand side diagram in Fig. 1 commutes, due to the fact that  $\text{pass}_1 = T; \text{pass}_2; T^*$ .

The following theorem is a direct consequence of [HP17, Theorem 2.1].

**Theorem 2.1.** With the notation introduced above, let  $(T, T^*)$  fulfil the satisfaction condition. Suppose that  $\text{TS}_2 \subseteq \text{TC}(Sig_2)$  is a complete test suite for fault model  $\mathcal{F}_2 = (S_2, \leq_2, Dom_2)$ . Define fault model  $\mathcal{F}_1$  on  $Sig_1$  by

$$\mathcal{F}_1 = (S_1, \leq_1, Dom_1), \text{ such that } T(S_1) = S_2 \text{ and } Dom_1 = \{S \mid T(S) \in Dom_2\}.$$

Then

$$\text{TS}_1 = T^*(\text{TS}_2)$$

is a complete test suite with respect to fault model  $\mathcal{F}_1$ . □

This theorem supports our justification of testing approaches for finite state machines in the context of CSP.

## 2.3. CSP and Refinement

### Communicating Sequential Processes

@todo

<sup>1</sup> We note that the operator “;” denotes the relational composition defined for functions or relations  $f \subseteq A \times B$ ,  $g \subseteq B \times C$  by  $f; g = \{(a, c) \in A \times C \mid \exists b \in B : (a, b) \in f \wedge (b, c) \in g\}$ . Note that  $f; g$  is evaluated from left to right (like composition of code fragments), as opposed to right-to-left evaluation which is usually denoted by  $g \circ f$ .

**Fig. 1.** Commuting diagrams reflecting the satisfaction condition.

### Normalised Transition Graphs for CSP Processes

As shown in [Ros94], any finite-state CSP process  $P$  can be represented by a *normalised transition graph*

$$G(P) = (N, \underline{n}, \Sigma, t : N \times \Sigma \rightarrow N, r : N \rightarrow \mathbb{PP}(\Sigma)),$$

with nodes  $N$ , initial node  $\underline{n} \in N$ , and process alphabet  $\Sigma$ . The partial *transition function*  $t$  maps a node  $n$  and an event  $e \in \Sigma$  to its successor node  $t(n, e)$ , if, and only if,  $(n, e)$  is in the domain of  $t$ , that is, there is a transition from  $n$  with label  $e$ . Normalisation of  $G(P)$  is reflected by the fact that  $t$  is a function.

A finite sequence of events  $s \in \Sigma^*$  is a *trace* of  $P$ , if there is a path through  $G(P)$  starting at  $\underline{n}$  whose edge labels coincide with  $s$ . The set of traces of  $P$  is denoted by  $\text{tr}(P)$ . If  $s \in \text{tr}(P)$ , then the process corresponding to  $P$  after having executed  $s$  is denoted by  $P/s$ . Since  $G(P)$  is normalised, there is a unique node reached by applying the events from  $s$  one by one, starting in  $\underline{n}$ . Therefore,  $G(P)/s$  is also well defined.

By  $[n]^0$  we denote the *fan-out* of  $n$ : the set of events occurring as labels in any outgoing transitions.

$$[n]^0 = \{e \in \Sigma \mid (n, e) \in \text{dom } t\}$$

We also use this notation for CSP processes:  $[P]^0$  is the set of events  $P$  may engage into, in other words, the initials of  $P$  after the empty trace of events, that is,  $\text{initials}(P/\langle \rangle)$  as defined in [Ros10].

The total function  $r$  maps each node  $n$  to its *refusals*  $r(n) = \text{Ref}(n)$ . Each element of  $r(n)$  is a set of events that the CSP process  $P$  might refuse to engage into, when in a process state corresponding to  $n$ . The number of refusal sets in  $\text{Ref}(P/s)$  specifies the degree of nondeterminism that is present in process state  $P/s$ : the more refusal sets contained in  $\text{Ref}(P/s)$ , the more nondeterministic is the behaviour in state  $P/s$ . If  $P/s$  is deterministic, its refusals coincide with the set of subsets of  $\Sigma - [P/s]^0$ , including the empty set.

For finite CSP processes, since the refusals of each process state are subset-closed [Hoa85, Ros10],  $\text{Ref}(P/s)$  can be re-constructed by knowing the set of *maximal refusals*  $\text{maxRef}(P/s) \subseteq \text{Ref}(P/s)$ . More formally, the maximal refusals  $\text{maxRef}(P/s)$  are defined as

$$\text{maxRef}(P/s) = \{R \in \text{Ref}(P/s) \mid \forall R' \in \text{Ref}(P/s) - \{R\} : R \not\subseteq R'\}$$

Conversely, with the maximal refusals at hand, we can reconstruct the refusals by subset-closure:

$$\text{Ref}(P/s) = \{R' \in \mathbb{P}(\Sigma) \mid \exists R \in \text{maxRef}(P/s) : R' \subseteq R\}.$$

To see that this approach works only for finite CSP processes, consider the example where  $\Sigma$  is infinite. In this case,  $\text{maxRef}(STOP/\langle \rangle)$  is empty, and so we cannot use this set to calculate the refusals of  $STOP$ , that is,  $\text{Ref}(STOP/\langle \rangle)$  as defined above. As with refusals, we also use the transition graph-oriented notation  $\text{maxRef}(n) \subseteq r(n)$  to denote the maximal refusals associated with graph state  $n$ : if  $n$  is the state reached in the transition graph by following the edge labels in trace  $s$ , then  $\text{maxRef}(n) = \text{maxRef}(P/s)$ .

Well-formed normalised transition graphs must not refuse an event of the fan-out of a state in *every* refusal applicable in this state; more formally,

$$\forall n \in N, e \in \Sigma : (n, e) \in \text{dom } t \Rightarrow \exists R \in \text{maxRef}(n) : e \notin R \quad (1)$$

**Fig. 2.** Normalised transition graph of CSP process  $P$  from Example 1.

By construction, normalised transition graphs reflect the *failures semantics* of finite-state CSP processes: the traces  $s$  of a process are exactly the sequences of transition labels associated with paths through the transition graph, starting at  $\underline{n}$ . The pairs  $(s, R)$  with  $s \in \text{tr}(P)$  and  $R \in r(G(P)/s)$  represent the failures of  $P$ .

**Example 1.** Consider the CSP process  $P$  defined below, and that the set of events  $\Sigma$  is  $\{a, b, c\}$ .

$$\begin{aligned} P &= a \rightarrow (Q \sqcap R) \\ Q &= a \rightarrow P \sqcap c \rightarrow P \\ R &= b \rightarrow P \sqcap c \rightarrow R \end{aligned}$$

Its transition graph  $G(P)$  is shown in Fig. 2. Process state  $P/\langle \rangle$  is represented there as Node\_0, with  $\{b, c\}$  as the only maximal refusal, since  $a$  can never be refused, and no other events are accepted. Having engaged into  $a$ , the transition emanating from Node\_0 leads to Node\_2 representing the process state  $P/a = Q \sqcap R$ . The internal choice operator induces several refusal sets derived from  $Q$  and  $R$ . Since these processes accept their initial events in external choice,  $Q \sqcap R$  induces just two maximal refusal sets  $\{b\}$  and  $\{a\}$ . Note that event  $c$  can never be refused, since it is not a member of any maximal refusal.

Having engaged into  $c$ , the next process state is represented by Node\_1. Due to normalisation, there is only a single transition satisfying  $t(\text{Node}_2, c) = \text{Node}_1$ . This transition, however, can have been caused by either  $Q$  or  $R$  engaging into  $c$ , so Node\_1 corresponds to process state  $Q/c \sqcap R/c = P \sqcap R$ . This is reflected by the two maximal refusals labelling Node\_1.

Similar considerations explain the other nodes and transition in Fig. 2.

### Tool Considerations

The FDR tool [GRABR14] supports model checking and semantic analyses of CSP processes. It provides an API [GRABR13] that can be used to construct normalised transition graphs for CSP processes.

The FDR graph nodes are labelled by *minimal acceptances* instead of maximal refusals as described above. Since such a minimal acceptance set is the complement of a maximal refusal, the function  $r$  mapping states to their refusals can be implemented by creating the complements of all minimal acceptances and then building all subsets of these complements. For practical applications, the subset closure is never constructed in an explicit way; instead, sets are checked with respect to containment in a maximal refusal.

## 2.4. Finite State Machines

To make this paper self-contained, we introduce definitions, notation, and facts about finite state machines (FSMs) that have been originally described in contributions on FSM testing, such as [PY11, PY14, Hie04].

A *Finite State Machine (FSM)* is a tuple  $M = (Q, \underline{q}, \Sigma_I, \Sigma_O, h)$  with state space  $Q$ , input alphabet  $\Sigma_I$ , and output alphabet  $\Sigma_O$ , where  $Q$ ,  $\Sigma_I$ , and  $\Sigma_O$  are finite and nonempty sets,  $\underline{q} \in Q$  denotes the initial state,  $h \subseteq Q \times \Sigma_I \times \Sigma_O \times Q$  is the transition relation, and  $(q, x, y, q') \in h$  if, and only if, there is a transition from  $q$  to  $q'$  with input  $x$  and output  $y$ . We use both set notation  $(q, x, y, q') \in h$  and Boolean notation  $h(q, x, y, q')$  for specifying that  $(q, x, y, q')$  is a transition in  $h$ .

The set of all FSMs with input alphabet  $\Sigma_I$  and output alphabet  $\Sigma_O$  is denoted  $\text{FSM}(\Sigma_I, \Sigma_O)$ .

We call  $x$  a *defined* input in state  $q$ , if there is a transition from  $q$  with input  $x$ . If every input of  $\Sigma_I$  is defined in every state,  $M$  is *completely specified*. If in every state  $q$  and for every output  $y \in \Sigma_O$ , an input  $x$  and a post-state  $q'$  satisfying  $h(q, x, y, q')$  exists, the FSM is called *output complete*.

FSM  $M$  is called a *deterministic FSM (DFSM)* if, for any state  $q$  and defined input  $x$ ,  $h(q, x, y, q')$  and  $h(q, x, y', q'')$  implies  $(y, q') = (y', q'')$ . Intuitively speaking, a specific input applied to a specific state uniquely determines both the post-state and associated output. If  $M$  is not deterministic, it is called a *nondeterministic FSM (NFSM)*. If there is no emanating transition for  $q \in Q$ , this state is called a *deadlock state*, and  $M$  *terminates in  $q$* . The set of deadlock states is denoted by  $\text{deadlock}(Q) \subseteq Q$ . The set of states that do not deadlock is denoted by  $\text{DF}(Q) = \{q \in Q \mid \exists(q', x, y, q'') \in h : q' = q\}$ .

The transition relation  $h$  can be extended in a natural way to input traces: let  $\bar{x}$  be an input trace and  $\bar{y}$  an output trace. Then  $(q, \bar{x}, \bar{y}, q') \in h$  if, and only if, there is a transition sequence from  $q$  to  $q'$  with input trace  $\bar{x}$  and output trace  $\bar{y}$ . If  $q$  is the initial state  $\underline{q}$ , such a transition sequence is called an *execution* of  $M$ . Executions are written in the notation

$$q_0 \xrightarrow{x_1/y_1} q_1 \xrightarrow{x_2/y_2} \dots \xrightarrow{x_k/y_k} q_k$$

with  $q_0 = \underline{q}$ ,  $h(q_{i-1}, x_i, y_i, q_i)$  for  $i = 1, \dots, k$ , and  $\bar{x} = x_1 \dots x_k$  and  $\bar{y} = y_1 \dots y_k$ .

The empty trace is denoted by  $\varepsilon$ , and  $(q, \varepsilon, \varepsilon, q) \in h$ , for any state  $q$ . The *language*  $L(M)$  of an FSM  $M$  is the set consisting of all possible pairs of input and output traces in  $M$ .  $L(M) = LM(\underline{q})$ , where for  $q \in Q$

$$L_M(q) = \{\bar{x}/\bar{y} \mid \exists q' \in Q : h(q, \bar{x}, \bar{y}, q')\}$$

An FSM  $M$  is called *observable* if in every state  $q$ , every existing post-state  $q'$  is uniquely determined by the I/O pair  $x/y$  satisfying  $h(q, x, y, q')$ . For observable state machines, the partial function

$$\text{-after-/-} : Q \times \Sigma_I \times \Sigma_O \rightarrow Q; \quad q\text{-after-}(x/y) = q' \Leftrightarrow h(q, x, y, q')$$

is well-defined. Again, it can be extended to I/O-traces  $\bar{x}/\bar{y}$  by repetitive application. Deterministic FSMs are always observable. Every non-observable FSM can be transformed into an observable one that has the same language [PH17]. The algorithm that can be used to make this transformation operates analogously to the algorithm for normalising transition graphs of CSP processes.

Two FSM  $M_1, M_2$  are *I/O-equivalent*, written  $M_1 \sim M_2$ , if, and only if, their languages coincide, i.e.  $L(M_1) = L(M_2)$ . FSM  $M_1$  is a *reduction of*  $M_2$ , written  $M_1 \preceq M_2$  if, and only if,  $L(M_1) \subseteq L(M_2)$ . I/O-equivalence is also called *trace equivalence* by some authors, see, e.g., [LvBP94].

FSMs can be composed in parallel by synchronising over their common input and output events. Let FSMs  $M_i = (Q_i, \underline{q}_i, \Sigma_I, \Sigma_O, h_i)$ ,  $i = 1, 2$  be defined over the same input and output alphabets. Then

$$M_1 \cap M_2 = (Q_1 \times Q_2, (\underline{q}_1, \underline{q}_2), \Sigma_I, \Sigma_O, h)$$

where the transition relation is specified by

$$h((q_1, q_2), x, y, (q'_1, q'_2)) \Leftrightarrow h_1(q_1, x, y, q'_1) \wedge h_2(q_2, x, y, q'_2)$$

By construction,  $L(M_1 \cap M_2) = L(M_1) \cap L(M_2)$ . Every execution

$$(\underline{q}_1, \underline{q}_2) \xrightarrow{x_1/y_1} (q_1^1, q_2^1) \xrightarrow{x_2/y_2} \dots \xrightarrow{x_k/y_k} (q_1^k, q_2^k)$$

of  $M_1 \cap M_2$  is composed of executions

$$\underline{q}_1 \xrightarrow{x_1/y_1} q_1^1 \xrightarrow{x_2/y_2} \dots \xrightarrow{x_k/y_k} q_1^k \text{ of } M_1 \text{ and } \underline{q}_2 \xrightarrow{x_1/y_1} q_2^1 \xrightarrow{x_2/y_2} \dots \xrightarrow{x_k/y_k} q_2^k \text{ of } M_2$$

In the next section, we show how normalised transition graphs can be encoded as an FSM.

### 3. Finite Complete Test Suites for CSP

#### 3.1. A Model Map from CSP Processes to Finite State Machines

We will now construct a model map for associating CSP processes represented by normalised transition graphs to finite state machines. The intuition behind this construction is that the finite state machine's input alphabet corresponds to *sets of inputs* that may be offered to a CSP process. Depending on the events contained in this set, the process may (1) accept all of them, (2) accept some of them while refusing others, and (3) refuse all of them. This is reflected in the FSM by outputs representing events that the process really has engaged in and an extra event  $\perp$  representing refusal, if the set of events has been blocked. Blocked sets of events are always associated with self-loop transitions: the state is not changed, because the corresponding CSP process also remains blocked in its current state.

More formally, we fix a finite CSP process alphabet  $\Sigma$  and consider a finite-state process  $P$  over this alphabet with normalised transition graph  $G(P) = (N, \underline{n}, \Sigma, t : N \times \Sigma \rightarrow N, r : N \rightarrow \mathbb{PP}(\Sigma))$ . Then the model map  $T$  maps  $P$  to the following observable FSM  $T(P) = (Q, \underline{q}, \Sigma_I, \Sigma_O, h)$  specified by

$$\begin{aligned} Q &= N \\ \underline{q} &= \underline{n} \\ \Sigma_I &= \mathbb{P}(\Sigma) - \{\emptyset\} \\ \Sigma_O &= \Sigma \cup \{\perp\} \\ h &= \{(n, A, e, n') \mid A \in \Sigma_I \wedge e \in A \wedge (n, e) \in \text{dom } t \wedge t(n, e) = n'\} \cup \\ &\quad \{(n, A, \perp, n) \mid A \in r(n) - \{\emptyset\}\} \end{aligned}$$

We say that FSM trace  $(x/s) \in L(T(P))$  and CSP trace  $s' \in \text{tr}(P)$  are *corresponding traces*, if  $s' = s \upharpoonright \Sigma$ . Observe that the FSM output trace  $s$  may contain deadlock events  $\perp$  that are not contained in the process alphabet  $\Sigma$ .

**Example 2.** For the CSP process  $P$  and its transition graph  $G(P)$  discussed in Example 1, the FSM  $T(P)$  is depicted in Fig. 3. For displaying its transitions, we used notation

$$(\text{condition}(A))/e$$

which stands for a set of transitions between the respective nodes: one transition per non-empty set  $A \subseteq \Sigma$  fulfilling the specified condition. The arrow

$$\text{Node\_0} \xrightarrow{(a \in A)/a} \text{Node\_2},$$

for example, stands for FSM transitions

$$\begin{aligned} \text{Node\_0} &\xrightarrow{\{a\}/a} \text{Node\_2} \\ \text{Node\_0} &\xrightarrow{\{a,b\}/a} \text{Node\_2} \\ \text{Node\_0} &\xrightarrow{\{a,c\}/a} \text{Node\_2} \\ \text{Node\_0} &\xrightarrow{\{a,b,c\}/a} \text{Node\_2} \end{aligned}$$

□

We are now in the position to state and prove the theorem about the model map fulfilling the satisfaction condition **SC1** introduced in Section 2.2. To this end, we first introduce five lemmas.

**Lemma 3.1.** Let  $s \in \text{tr}(P)$  and  $n = G(P)/s$  be the node of  $G(P)$  corresponding the process state  $P/s$ . Then for any  $x \in \Sigma_I$ ,  $y \in \Sigma_O$ :

$$\begin{aligned} (n, x, y, n') \in h &\Leftrightarrow (y \in x \wedge s.y \in \text{tr}(P) \wedge n' = G(P)/s.y) \vee \\ &\quad (y = \perp \wedge (s, x) \in \text{Fail}(P) \wedge n' = n) \end{aligned}$$

*Proof.* Let  $s' = s.y \upharpoonright \Sigma$ . We consider the following two cases:

**Fig. 3.** FSM resulting from applying the model map to CSP process  $P$  from Example 1.

1. Suppose  $y = e$  for some  $e \in \Sigma$ . Then  $s' = s.e$ . By definition of  $h$ , we have

$$\begin{aligned} (n, x, e, n') \in h &\Leftrightarrow e \in x \wedge (n, e) \in \text{dom } t \wedge n' = t(n, e) \\ &\Leftrightarrow e \in x \wedge s.e \in \text{tr}(P) \wedge n' = G(P)/s.e \end{aligned}$$

2. Suppose  $y = \perp$ . Then  $s' = s$ , and we can derive

$$\begin{aligned} (n, x, \perp, n') \in h &\Leftrightarrow x \in \text{Ref}(P/s) \wedge n' = n \\ &\Leftrightarrow (s, x) \in \text{Fail}(P) \wedge n' = n \end{aligned}$$

□

**Lemma 3.2.** Let  $x/y \in (\Sigma_I \times \Sigma_O)^*$  and  $s = y \upharpoonright \Sigma$ . Then

$$x/y \in L(T(P)) \Rightarrow s \in \text{tr}(P) \wedge \underline{q}\text{-after-}x/y = G(P)/s.$$

*Proof.* We prove the lemma by induction on  $\#(x/y)$ , the length of  $x/y$ . For the base case, suppose that  $x/y = \varepsilon$ , then  $s = \varepsilon$  and  $\underline{q}\text{-after-}x/y = \underline{n} = G(P)/\varepsilon$ . For the induction hypothesis, suppose the statement holds for all  $x/y \in (\Sigma_I \times \Sigma_O)^*$  with  $\#(x/y) = k$ , for some  $k \geq 0$ . Let  $x/y \in (\Sigma_I \times \Sigma_O)^*$  with  $\#(x/y) = k$  and  $x'/y' \in \Sigma \times \Sigma_O$ . To perform the induction step, let  $y \upharpoonright \Sigma = s$  and  $y.y' \upharpoonright \Sigma = s'$ . Then by the induction hypothesis we have  $s \in \text{tr}(P)$  and  $\underline{q}\text{-after-}x/y = G(P)/s$ . Since  $x.x'/y.y' \in L(T(P))$ , there is a transition  $(G(P)/s', x', y', n) \in h$  and  $n = \underline{q}\text{-after-}x/y$ . By Lemma 3.1 we have  $s' = s.y' \in \text{tr}(P) \wedge \underline{q}\text{-after-}x.x'/y.y' = G(P)/s'$ . □

**Lemma 3.3.** Let  $x/y \in (\Sigma_I \times \Sigma_O)^*$  and  $x/y \in L(T(P))$ . Let  $x'/y' \in \Sigma_I \times \Sigma_O$ . Then

$$x.x'/y.y' \in L(T(P)) \Leftrightarrow (y' \in x' \wedge (y.y') \upharpoonright \Sigma \in \text{tr}(P)) \vee (y' = \perp \wedge (y \upharpoonright \Sigma, x') \in \text{Fail}(P)).$$

*Proof.* Let  $x/y \in (\Sigma_I \times \Sigma_O)^*$  and  $x/y \in L(T(P))$ . Let  $x'/y' \in \Sigma_I \times \Sigma_O$ . Then by Lemma 3.2, we have  $s = y \upharpoonright \Sigma \in \text{tr}(P)$  and  $G(P)/s = \underline{q}$ -after- $x/y$ . From Lemma 3.1 we have the following:

$$\begin{aligned} & x.x'/y.y' \in L(T(P)) \\ \Leftrightarrow & \exists n' \in Q : (G(P)/s, x', y', n') \in h \\ \Leftrightarrow & (y' \in x' \wedge s.y' \in \text{tr}(P)) \vee (y' = \perp \wedge (s, x') \in \text{Fail}(P)) \\ \Leftrightarrow & (y' \in x' \wedge (y.y') \upharpoonright \Sigma \in \text{tr}(P)) \vee (y' = \perp \wedge (y \upharpoonright \Sigma, x') \in \text{Fail}(P)) \end{aligned}$$

□

**Lemma 3.4.** For any  $s \in \Sigma^*$ ,

$$s \in \text{tr}(P) \Leftrightarrow \exists x \in \Sigma_I^* : x/s \in L(T(P)).$$

*Proof.* Let  $s \in \Sigma^*$ . We prove the lemma by induction on  $\#s$  the length of  $s$ . Suppose  $s = \varepsilon$ , then  $s \in \text{tr}(P) \wedge x = \varepsilon \Leftrightarrow x/s \in L(T(P))$ . Suppose the statement holds for all  $s \in \Sigma^*$  with  $\#s = k$ , for some  $k \geq 0$ . Let  $s \in \Sigma^*$  with  $\#s = k$  and  $e \in \Sigma$ . Then

$$\begin{aligned} & s.e \in \text{tr}(P) \\ \Leftrightarrow & s \in \text{tr}(P) \wedge s.e \in \text{tr}(P) \\ \Leftrightarrow & \exists x \in \Sigma_I^* : x/s \in L(T(P)) \wedge s.e \in \text{tr}(P) \\ \Rightarrow & \exists x \in \Sigma_I^* : x.\{e\}/s.e \in L(T(P)) \quad [\text{Lemma 3.3}] \\ \Rightarrow & \exists x \in \Sigma_I^* : x/s.e \in L(T(P)) \\ \\ & \exists x \in \Sigma_I^* : x/s.e \in L(T(P)) \\ \Leftrightarrow & \exists x \in \Sigma_I^* \wedge \exists x' \in \Sigma_I : x/s \in L(T(P)) \wedge x.x'/s.e \in L(T(P)) \\ \Rightarrow & s.e \in \text{tr}(P) \quad [\text{Lemma 3.3}] \end{aligned}$$

□

**Lemma 3.5.** For any  $s \in \Sigma^*$  and  $x' \in \Sigma_I$ ,

$$(s, x') \in \text{Fail}(P) \Leftrightarrow \exists x \in \Sigma_I^* : x.x'/s.\perp \in L(T(P))$$

*Proof.*  $\forall s \in \Sigma^*, x' \in \Sigma_I$ :

$$\begin{aligned} & \exists x \in \Sigma_I^* : x.x'/s.\perp \in L(T(P)) \\ \Leftrightarrow & \exists x \in \Sigma_I^* : x/s \in L(T(P)) \wedge x.x'/s.\perp \in L(T(P)) \\ \Leftrightarrow & (s, x') \in \text{Fail}(P) \quad [\text{Lemma 3.3 and 3.4}] \end{aligned}$$

□

**Theorem 3.1.** Let  $P, Q$  be two CSP processes over the same alphabet  $\Sigma$ . Then  $T(Q) \preceq T(P) \Leftrightarrow P \sqsubseteq_F Q$

*Proof.* Suppose  $T(Q) \preceq T(P)$ . Let  $s \in \Sigma^*, x' \in \Sigma_I$ . Then by Lemma 3.4 and Lemma 3.5

$$\begin{aligned} s \in \text{tr}(Q) & \Leftrightarrow \exists x \in \Sigma_I^* : x/s \in L(T(Q)) \\ & \Rightarrow \exists x \in \Sigma_I^* : x/s \in L(T(P)) \\ & \Leftrightarrow s \in \text{tr}(P) \\ \\ (s, x') \in \text{Fail}(Q) & \Leftrightarrow \exists x \in \Sigma_I^* : x.x'/s.\perp \in L(T(Q)) \\ & \Rightarrow \exists x \in \Sigma_I^* : x.x'/s.\perp \in L(T(P)) \\ & \Leftrightarrow (s, x') \in \text{Fail}(P) \end{aligned}$$

Hence

$$T(Q) \preceq T(P) \Rightarrow P \sqsubseteq_F Q$$

Now suppose  $P \sqsubseteq_F Q$ . We prove by induction on  $\#(x/y)$  that for any  $x/y \in (\Sigma_I \times \Sigma_O)^*$ ,  $x/y \in L(T(Q)) \Rightarrow x/y \in L(T(P))$  holds. It is trivial if  $\#(x/y) = 0$ . Suppose  $x/y \in L(T(Q)) \Rightarrow x/y \in L(T(P))$  holds for any  $x/y \in (\Sigma_I \times \Sigma_O)^*$  of length  $k \geq 0$ . For any  $x/y \in (\Sigma_I \times \Sigma_O)^*$  of length  $k$  and for any  $x'/y' \in \Sigma_I \times \Sigma_O$ . Let  $s = y \upharpoonright \Sigma$  and  $s' = (y.y') \upharpoonright \Sigma$ . Then by Lemma 3.3 and  $P \sqsubseteq_F Q$  we have

$$\begin{aligned} & x.x'/y.y' \in L(T(Q)) \\ \Rightarrow & x/y \in L(T(Q)) \wedge ((y' \in x' \wedge s' \in \text{tr}(Q)) \vee (y' = \perp \wedge (s, x) \in \text{Fail}(Q))) \\ \Rightarrow & x/y \in L(T(P)) \wedge ((y' \in x' \wedge s' \in \text{tr}(P)) \vee (y' = \perp \wedge (s, x) \in \text{Fail}(P))) \\ \Rightarrow & x.x'/y.y' \in L(T(P)) \end{aligned}$$

Hence

$$P \sqsubseteq_F Q \Rightarrow T(Q) \preceq T(P)$$

.  $\square$

### 3.2. A Test Case Map from Finite State Machines to CSP Processes

#### FSM Test Cases

Following [PY14], an *adaptive FSM test case*

$$tc_{\text{FSM}} = (Q, \underline{q}, \Sigma_I, \Sigma_O, h, in)$$

is a nondeterministic, observable, output-complete, acyclic FSM which only provides a single input in a given state. Running in FSM intersection mode with the SUT, the test case provides a specific input to the SUT; this input is determined by the current state of the test case. It accepts every output and transits either to a fail-state FAIL, if the output is wrong according to the test objectives, or to the next test state uniquely determined by the processed input/output pair. Another state PASS indicates that the test has been completed without failure. Both FAIL and PASS are termination states, that is, they do not have any outgoing transitions.

Since the test case state determines the input for all of its outgoing transitions, this input is typically used as a state label, and the outgoing transitions are just labelled by the possible outputs. A function  $in : Q - \{\text{PASS}, \text{FAIL}\} \rightarrow \Sigma_I$  maps the states to these inputs. Termination states of the FSM are not labelled with further inputs.

There is no requirement that an FSM test case running in intersection mode against an FSM  $M$  acting as SUT should *always* reach the PASS state. Since the SUT may be nondeterministic, it may perform a joint test execution that blocks before the test case's PASS state is reached. In such a case, the result of the test execution is *inconclusive*. Due to nondeterminism, for  $M$  to pass a test case, it has to checked that *every possible* test execution of  $tc_{\text{FSM}}$  against  $M$  terminates either in PASS, or that the result remains inconclusive. If one execution ends in FAIL, the test verdict is FAIL. More formally,

$$M \text{ pass } tc_{\text{FSM}} \equiv (\forall x/y \in L(M) \cap L(tc_{\text{FSM}}) : \underline{q}\text{-after-}(x/y) \neq \text{FAIL}).$$

**Example 3.** Consider the FSM test case depicted in Fig. 4 which is specified for the same input and output alphabets as defined for the FSM presented in Example 2. The test case is passed by the FSM from Example 2, because intersecting the two state machines results in an FSM which always reaches the PASS state.  $\square$

#### CSP Test Cases

A *CSP test case*  $tc_{\text{CSP}}$  is a terminating process with alphabet  $\Sigma \cup \{\dagger, \perp, \checkmark\}$ , where the extra events stand for (1) test verdict FAIL ( $\dagger$ ), (2) timeout ( $\perp$ ), and (3) test verdict PASS ( $\checkmark$ ). The test case runs in parallel with the SUT  $P$ , synchronising over all events from the visible alphabet  $\Sigma$  of  $P$ . This is expressed by the formula

$$P \parallel [\Sigma] \parallel tc_{\text{CSP}}.$$

In analogy to FSM test cases, a CSP process  $P$  passes a test case  $tc_{\text{CSP}}$  if the traces of the parallel

$$P \text{ pass } tc_{\text{CSP}} \equiv (\forall s \in \text{tr}(P \parallel [\Sigma]) tc_{\text{CSP}}) : (s \upharpoonright \{\dagger\}) = \varepsilon)$$

## Test Case Map

$$\begin{aligned} tc_{\text{CSP}} &= tc(\underline{q}) \\ tc(q) &= (e : A(q) \rightarrow tc(q\text{-after-}(in(q)/e))) \\ &\quad \square (e : A_{\text{PASS}}(q) \rightarrow \checkmark \rightarrow Skip) \\ &\quad \square (e : A_{\text{FAIL}}(q) \rightarrow \dagger \rightarrow Skip) \end{aligned}$$

$$\begin{aligned} A(q) &= \{a \in \text{in}(q) \cup \{\perp\} \mid q\text{-after-}(\text{in}(q)/a) \notin \{\text{PASS}, \text{FAIL}\}\} \\ A_{\text{PASS}}(q) &= \{a \in \text{in}(q) \cup \{\perp\} \mid q\text{-after-}(\text{in}(q)/a) = \text{PASS}\} \\ A_{\text{FAIL}}(q) &= \{a \in \text{in}(q) \cup \{\perp\} \mid q\text{-after-}(\text{in}(q)/a) = \text{FAIL}\} \end{aligned}$$

Intuitively speaking,  $tc_{CSP}$  offers in each test step the same events to the CSP process to be tested as the FSM test case offers to the FSM under test. These events are specified in each non-terminating test step by  $in(q)$ , where  $q$  is the current state of the FSM test case  $tc_{FSM}$ . While the FSM test case offers these events a single set-valued member of the input alphabet  $\Sigma_I$  to the FSM under test, the CSP test offers the same to the SUT by means of an external choice, so that it just depends on the SUT which event to choose. In addition to the events from  $in(q)$ , the CSP test case accepts the event  $\perp$  which is not shared with the SUT but represents a timeout event provided by the testing environment to indicate that the SUT is blocked without accepting any of the events in  $in(q)$ .

The events offered/accepted by the CSP test in state  $tc(q)$  are partitioned into 3 sets  $A(q)$ ,  $A_{PASS}(q)$ , and  $A_{FAIL}(q)$ . The disjointness of these sets is a consequence of the fact that the FSM test case is observable: if  $tc_{FSM}$  can transit, for example, from  $q$  to FAIL with I/O  $in(q)/a$ , then there exists no other transition from  $q$  which is also labelled by  $in(q)/a$ .

**Example 4.** The FSM test case  $tc_{FSM}$  shown in Fig. 4 is mapped by  $T^*$  to the following CSP test case.

$$\begin{aligned} T^*(tc_{FSM}) &= P_1 \\ P_1 &= (e : \{b, c, \perp\} \bullet e \rightarrow \dagger \rightarrow Skip) \square (a \rightarrow P_2) \\ P_2 &= (e : \{a, b, \perp\} \bullet e \rightarrow \dagger \rightarrow Skip) \square (c \rightarrow P_3) \\ P_3 &= (e : \{a, b\} \bullet e \rightarrow \dagger \rightarrow Skip) \square (\perp \rightarrow P_4) \square (c \rightarrow P_5) \\ P_4 &= (e : \{b, c, \perp\} \bullet e \rightarrow \dagger \rightarrow Skip) \square (a \rightarrow \checkmark \rightarrow Skip) \\ P_5 &= (e : \{a, b, \perp\} \bullet e \rightarrow \dagger \rightarrow Skip) \square (c \rightarrow \checkmark \rightarrow Skip) \end{aligned}$$

□

The following theorem shows the validity of the satisfaction condition **SC2** regarding the test case map, the model map, and the pass conditions for tests on CSP level and FSM level.

**Theorem 3.2.** Fixing a CSP process alphabet  $\Sigma$ , the model map  $T : Sig_1 \rightarrow FSM$  and the test case map  $T^* : TC(FSM) \rightarrow TC(CSP)$  fulfil satisfaction condition **SC2** in the sense that

$$\forall P \in Sig_1, tc_{FSM} \in TC(FSM) : T(P) \text{ pass}_2 tc_{FSM} \Leftrightarrow P \text{ pass}_1 T^*(tc_{FSM})$$

*Proof.* Let  $T(P) = (Q, \underline{q}, \Sigma_I, \Sigma_O, h)$  and  $tc_{FSM} = (Q', \underline{q}', \Sigma_I, \Sigma_O, h', in)$ . We show by induction over the length of  $s \in \Sigma_O^*$  that the following assertions hold for all  $s$ .

1. For every pass-trace  $x/s \in L(T(P)) \cap L(tc_{FSM})$ , there exists a pass-trace  $u \in \text{tr}(P \parallel [\Sigma] \parallel T^*(tc_{FSM}))$ , such that  $u \upharpoonright \Sigma$  corresponds to  $x/s$ .
2. For every fail-trace  $x/s \in L(T(P)) \cap L(tc_{FSM})$ , there exists a fail-trace trace  $u \in \text{tr}(P \parallel [\Sigma] \parallel T^*(tc_{FSM}))$ , such that  $u \upharpoonright \Sigma$  corresponds to  $x/s$ .
3. For all  $x/s \in L(T(P))$ , the graph nodes of  $G(P)$  and the states of  $T(P)$  are related by

$$G(P)/(s \upharpoonright \Sigma) = \underline{q}\text{-after-}(x/s).$$

4. FSM test  $tc_{FSM}$  and CSP test  $T^*(tc_{FSM})$  perform consistent state changes, in the sense that

$$\begin{aligned} x/s \in L(T(P)) \cap L(tc_{FSM}) \wedge \underline{q}'\text{-after-}(x/s) \notin \{\text{PASS}, \text{FAIL}\} \Rightarrow \\ T^*(tc_{FSM})/(s \upharpoonright \Sigma) = tc(\underline{q}'\text{-after-}(x/s)), \end{aligned}$$

where  $tc(q)$  has been defined above with the test case map.

Proof of 1 and 2 obviously proves the theorem; assertions 3 and 4 are needed to perform the induction argument.

For the base case,  $s$  is the empty trace  $\varepsilon$ , so  $x/s$  is empty as well. We have  $G(P)/\varepsilon = \underline{n} = \underline{q}$ , due to the definition of the model map; this proves Assertion 3 for the base case. FSM test case  $tc_{FSM}$  resides in its initial state  $\underline{q}'$ . By definition of the test case map above,  $T^*(tc_{FSM})$  has initial CSP process state  $tc(\underline{q}')$ ; this proves Assertion 4 for the base case  $\#s = 0$ . For assertions 1 and 2, there is nothing to prove: no test can pass or fail on the empty trace.

For the induction hypothesis, assume that the four assertions have been proven for  $\#s \leq k$  with  $0 \leq k$ .

For the induction step, assume that the FSM  $T(P)$  has run through trace  $x/s \in L(T(P)) \cap L(tc_{FSM})$

such that  $\#s \leq k$  and  $\underline{q}\text{-after-}(x/s) = q \in N$ . Moreover, the FSM test case  $tc_{\text{FSM}}$  fulfils  $\underline{q}'\text{-after-}(x/s) = q'$  for a uniquely defined state  $q' \in Q'$ . The induction hypothesis gives us  $G(P)/(s \upharpoonright \Sigma) = \underline{q}\text{-after-}(x/s) = q$  from Assertion 3 and  $T^*(tc_{\text{FSM}})/(s \upharpoonright \Sigma) = tc(q')$  from Assertion 4. FSM test  $tc_{\text{FSM}}$  will offer input  $in(q')$  to the FSM  $T(P)$  which is being tested. We distinguish two cases for the outcomes of the resulting test step.

**Case 1.**  $(x.in(q'))/(s.\perp) \in L(\underline{q}\text{-after-}(x/s))$ .

By construction of  $T(P)$ , this is exactly the case if  $in(q') \in r(G(P)/(s \upharpoonright \Sigma)) - \{\emptyset\}$ . By construction of  $T(P)$ , this FSM will perform a self-loop transition labelled by  $in(q')/\perp$  and therefore remain in  $q$ . For  $P$ , the corresponding behaviour is to refuse all events from  $in(q')$ , so  $q$  also remains as the current state in  $G(P)/(s \upharpoonright \Sigma)$ . This proves Assertion 3 for the induction step, Case 1.

Since  $tc_{\text{FSM}}$  is output complete,  $in(q')/\perp \in L(q')$ . Depending on the nature of the test case,  $q'\text{-after-}(in(q')/\perp)$  is one of the deadlock states PASS, FAIL, or it is a non-blocking FSM state, say,  $q''$ . Since  $tc_{\text{FSM}}$  is observable, however, this post-state is uniquely determined. Since the sets  $A(q)$ ,  $A_{\text{PASS}}(q)$ , and  $A_{\text{FAIL}}(q)$  are disjoint,  $T^*(tc_{\text{FSM}})$  has exactly one choice to proceed and will come to the post-states that are analogous to those of  $tc_{\text{FSM}}$ : if  $tc_{\text{FSM}}$  terminates in PASS(FAIL), then  $T^*(tc_{\text{FSM}})$  will produce the events  $\perp$  followed by  $\checkmark(\dagger)$  and terminate. If  $tc_{\text{FSM}}$  transits with  $in(q)/e$  to  $q''$ , CSP test case  $T^*(tc_{\text{FSM}})$  will perform  $e \in A(q)$  as well and continue like process  $tc(q'\text{-after-}(in(q')/\perp))$  with  $q'\text{-after-}(in(q')/\perp) = q''$ . Since  $\perp, \checkmark, \dagger$  are not contained in  $\Sigma$ , the CSP process  $P$  cannot block these transitions of  $T^*(tc_{\text{FSM}})$ , since we have assumed  $P$  to be non-divergent. This shows that  $tc_{\text{FSM}}$  and  $T^*(tc_{\text{FSM}})$  engage into the same pass/fail/continue step, as was to be shown. This proves assertions 1,2,4 for Case 1.

**Case 2.**  $(x.in(q'))/(s.e) \in L(\underline{q}\text{-after-}(x/s))$  with  $e \in in(q') \subseteq \Sigma$ .

By construction of  $T(P)$ , this case applies whenever  $e \in A \wedge (n, e) \in \text{dom } t$ . Also by construction, FSM  $T(P)$  will transit to  $t(q, e)$  (recall that  $q = G(P)/(s \upharpoonright \Sigma)$ , so  $q\text{-after-}(in(q')/e) = u$  for a uniquely defined state  $u = t(q, e) \in N$ ). Since  $G(P)/(s \upharpoonright \Sigma)$  will also transit to  $u$  by definition of  $t$ , this proves the induction step for Assertion 3.

With the same argument as in Case 1, we conclude that  $tc_{\text{FSM}}$  and  $tc(q')$  can perform equivalent test steps, leading to PASS or FAIL deadlock state, or to continuation of the test in the new state  $q'\text{-after-}(in(q')/e)$ . This proves the induction step for assertions 1,2,4 in Case 2 and completes the proof.  $\square$
